

Part 2 - Elements Per Thread

[Not to scale]

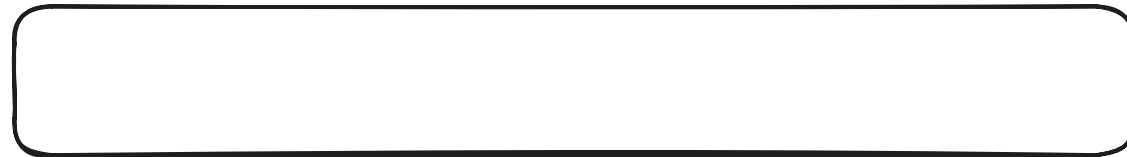

Workgroup Size = 64

Array size = 2^{22}

Array A

Array B

(Target) Array C

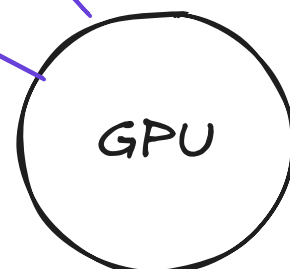

EPT = 8

WGZ = 64

WorkItems

Each separate work-item / thread is responsible for 8 elements

Divided the array size, by EPT:

$$2^{22} / 8 = 524288$$

How many 'chunks' are left, this value can now be divided by the WGZ

$$524288 / 64 = 8192$$

This is the number of work-item / threads that need to be launched for that specific kernel
